ABSTRACT
The antilithiatic effect of Relith (Polyherbal formulation) was determined on ethylene glycol induced lithiasis in male albino rats. The lithiasis was induced to rats by oral consumption of ethylene glycolated water (0.75v/v) for 28 days. Relith (500mg/kg) was administered orally from 1st day for preventive regimen and from 15th day for curative regimen. The urinary ionic parameters were altered by ethylene glycol, which elevated the calcium, oxalate, inorganic phosphate, protein concentration in urine. The Relith significantly (P<0.01) reduced the elevated levels of these ions and protein in urine. Also the extract significantly (P<0.01) elevated the urinary concentration of magnesium. The elevated serum creatinine levels of lithiatic rats were reduced by prophylactic and curative regimen of extract treatment. The histological findings also showed improvement after treatment with the extract. These observations enable to conclude that the curative and preventive properties of Relith against ethylene glycol induced urolithiasis.

Keywords: Relith, Polyherbal formulation, ethylene glycol induced lithiasis.

INTRODUCTION
Kidney stone formation or urolithiasis is a complex process that is a consequence of an imbalance between promoters and inhibitors in the kidneys[1]. Even though the technological developments in the present medical practice the formation and growth of renal calculi continues to afflict humankind. Though various kinds of stone have been identified, calcium stones are the most common in human as well as rats [2]. Urinary stone disease is a common disorder estimated to occur in approximately 12% of the world population, with a recurrence rate of 70-81% in males and 47- 60% in females [3]. The recurrence of urolithiasis represents a major problem as patients who have formed one stone are more likely to form another. The standard drugs used to prevent urolithiasis are not effective in all patients, and many of them have adverse effects that compromise their
long term use. The present day management of nephrolithiasis with open renal surgery is unusual and rarely used only since the introduction of Extracorporeal Shock Wave Lithotripsy (ESWL) which has almost become the standard procedure for eliminating kidney stones.

However, in addition to the traumatic effect of shockwaves, persistent residue stone fragments and the possibility of infection suggests that ESWL may cause acute renal injury, a decrease in renal function and an increase in stone recurrence \[^{4,5}\]. Hence the search for antilithiatic drugs to be effective without side effects from natural sources has gained great potential.

Relith is a poly herbal formulaition which contain Pasanbhed, Punarnava, Gokshur, Ashwagandha, Varuna, etc \[^{6,7,8}\].

Above mentioned herbs, are used as demulcent, aphrodisiac, diuretic, urinary tonic and hepatoprotective substance. A literature survey revealed that Relith (Polyherbal formulation) is endowed with various chemical components such as alkaloids, phytosterols, mucilage and fixed oil etc. which possibly contribute to its vast uses in folklore medicine \[^{7,8}\]. The present study was planned to evaluate the antilithiatic activity of Relith on ethylene glycol induced calcium oxalate urolithiasis in male rats.

**MATERIALS AND METHODS**

**Materials**

The capsules of Relith was gifted from Prakruti Pharma, Surat. And Cystone is purchased from the local market, Bardoli.

**Experimental Animals**

Male albino rats of wistar strain weighing between 150-200gm were used, the animals were fed with commercial rat feed pellets and were given water ad libitum. Animals were housed in plastic cages with filter tops under controlled conditions of 12:12 light dark cycle, 50% humidity and 28°C. All animal experiments and maintenance were carried out according to the ethical guidelines suggested by the IAEC of
Vidyabharti Trust College of Pharmacy, Umrankh, Bardoli. (Approval no. VBT/IAEC/10/11/34)

Pharmacological Screening for Anti Urolithiatic Activity

Animals were divided in to five groups containing six animals in each group. Group I served as normal control and received regular rat food and drinking water ad libitum. Ethylene glycol (0.75%) in drinking water was fed to Group II-V for induction of renal calculi till 28\textsuperscript{th} day. Group II served as lithiatic control and received vehicle 1% tween 80, Group III received standard antiurolithiatic drug, cystone (750mg/kg) from 15\textsuperscript{th} day till 28\textsuperscript{th} day \cite{9,10}. Group IV received Relith (Polyherbal formulation, 500mg/kg) from 15\textsuperscript{th} day till 28\textsuperscript{th} day and served as curative regimen. Group V received Relith (Polyherbal formulation, 500mg/kg) from 1\textsuperscript{st} day till 28\textsuperscript{th} day and served as preventive regimen. All drugs were given once daily by oral route using gastric tube. On day 28, animals of all the groups were kept in metabolic cages and urine samples were collected for 24h and analyzed for calcium, magnesium, oxalate, inorganic phosphate, protein and creatinine using standard methods \cite{2,11-14}. The serum creatinine levels and urinary output volumes of all groups were also noted.

Histopathological Studies

To confirm the incidence of lithiasis, the animals were sacrificed and their kidneys were isolated and subjected to histopathological studies. The kidneys were washed, weighed and fixed rapidly with 10% neutralized formalin (pH7.4), and soaked in paraffin, cut at 5 m intervals and the slices were stained with hematoxylin and eosin. Tissue slices were photographed using optical microscopy and observed the pathological changes \cite{15}.

Statistical Analysis

The results were expressed as mean ± SD. Statistical analysis was performed by ANOVA test for multiple comparisons followed by Dunnett’s test and P<0.05 was considered as significant.
RESULTS

The urinary output of the control and experimental rats on day 28 are shown in Fig1. The urinary volume of normal rats was 5.79±0.13 ml/day/rat whereas in the ethylene glycol alone treated rats it was statistically reduced (P<0.01) 3.55±0.11ml/day/rat. However in the Relith treated curative and preventive regimen groups, the urinary outputs increased significantly (P<0.01) to 5.07±0.17 and 5.15±0.03ml/day/rat respectively. The chronic administration of 0.75%v/v ethylene glycol aqueous solution to male rats resulted in hyperoxaluria. And the calcium, Oxalate, phosphate and protein excretion were grossly increased. However, supplementation with Relith significantly (P<0.01) lowered the elevated levels of calcium, oxalate, phosphate and protein excretion in urine of curative and preventive regimen groups.

Contrary to this, in lithiatic control group the magnesium excretion was gradually decreased following ethylene glycol treatment. Subsequent administration of the extract enhanced the magnesium excretion significantly (P<0.01) in both regimens (Table 1).

Values are expressed as Mean±SD for six animals in each group, One way ANOVA followed by Dennett’s test. ** p<0.01, Values are significantly different from Lithiatic control group. * p<0.01, Values are significantly different from Normal control group.

The creatinine clearance of lithiatic control rats were decreased, but it was improved significantly (P<0.01) in standard and extract treated groups. The data on serum analysis showed significant increase (P<0.01) in creatinine levels in litiatic control rats when compared to normal rats. After treated with Relith (Polyherbal Formulation), serum creatinine levels were restored to normal limits (Table 2).

Histopathological studies of kidneys clearly revealed that the tissue samples from the control group shows tubules with single epithelial lining along the margin and were of
normal size. In lithiatic control, all the tubules showed the presence of crystals, there was marked dilation of the tubules and total degeneration of epithelial lining with infiltration of inflammatory cells into the interstitial space. But kidney specimen from standard and extract treated groups showed characters similar to the normal control group (Figure 2).

Histopathology of Kidney of urolithiatic rats
DISCUSSION

It has been well documented that calculi disease affects 12% of the world population. The disease is frequently rising in the western countries, attributed to their lifestyle and dietary habits [16]. Herbal drugs claim many promising remedies in urolithiasis. Systematic and scientific evaluation has been done only few. An attempt is made in this direction using Relith, a Polyherbal formulation. In the present study, male rats were selected to induce urolithiasis because the urinary system of male rats resembles that of humans [17].

Urinary super saturation with respect to stone-forming constituents is generally considered to be one of the causative factors in calculogenesis. Administration of ethylene glycol (0.75%, v/v) to young male albino rats for 14 day period forms renal calculi composed mainly of calcium oxalate. The biochemical mechanisms for this process are related to an increase in the urinary concentration of oxalate. Stone formation in ethylene glycol fed animals is caused by hyperoxaluria, which causes increased renal retention and excretion of oxalate [18, 19].

It has been reported that the kidneys are the principle target organ for ethylene glycol toxicity and administration of ethylene glycol for more than 4 weeks resulted in insignificant urinary oxalate excretion and deposition of crystals in kidney [20], hence in our study ethylene glycol was chosen to induce lithiasis. Following the induction of lithiasis the urinary volume and composition were found to be altered. In our study also the urinary output was markedly decreased in lithiatic control rats on day 28, however in plant extract and standard treated rats the urinary volumes were increased when compared to that lithiatic Group. This suggested that relith might have mild diuretic effect. Following ethylene glycol administration the excretion of calcium, oxalate, phosphate and protein were found to be increased in lithiatic group while in standard, curative and preventive groups these levels were significantly decreased (P<0.01).

On contrary to this the magnesium level was decreased in lithiatic group while in standard and extract treated groups those levels were increased significantly (P<0.01).
The serum creatinine levels of extract treated rats restored to normal limits and the creatinine clearance was also found to be improved. The findings of the histopathological studies suggested that no microcrystalline deposition and kidney damage in the Relith treated groups. All these observations enabled us to confirm the inhibitory and curative potential of Relith on ethylene glycol induced lithiasis.

The various phytocounstituents in Relith may be the reason for antilithiatic activity against ethylene glycol induced lithiasis. In conclusion, the Relith, A olyherbal formulation has both prophylactic as well as curative property in urolithiasis of rats.

ACKNOWLEDGEMENT

The authors of the present study were very thankful to Rutal Laboratories, Atit Laboratories, Bardoli and Vidyabharti Trust College of Pharmacy, Umrahk, Bardoli for making this study possible by providing all kind of facilities at each and every step.
